

Reflection on Adolescence or Middle Adulthood

Posted on October 2, 2018

Adolescence represents the stage between childhood and adulthood in which puberty, brain development, social expectations, and increasing independence create major transitions. The original reflection described this period as a time of biological, sexual, emotional, intellectual, and social change and connected the experience to Erik Erikson's psychosocial stage of identity versus role confusion. That connection remains appropriate because adolescence often requires a person to ask who they are, how they differ from their parents, which values they accept, and what kind of adult they may become. My own experience was shaped by discomfort with bodily changes, a desire for privacy, conflict over independence, and pressure to behave more maturely before I felt prepared. Looking back, I can see that the confusion was not evidence that something was fundamentally wrong with me. It reflected a developmental process in which an earlier childhood identity was becoming insufficient while a stable adult identity had not yet formed (Blakemore, 2018).

Adolescence as a Period of Transition

Puberty produces visible physical changes, but adolescence is not only a biological event. It also changes how a person is treated by family, teachers, friends, and society. Expectations increase, privileges and responsibilities are renegotiated, and peer relationships become more emotionally significant. Cognitive development allows adolescents to think more abstractly, imagine different futures, question rules, and compare their private self with the person they appear to be in public. These abilities can support creativity and moral reasoning, but they can also intensify self-consciousness. A small criticism may feel like a judgment of the whole self, and ordinary uncertainty may be experienced as proof that everyone else is more confident. My adolescence contained this tension. I wanted greater autonomy, yet I also wanted the protection and certainty associated with childhood. I interpreted the demand to "grow up" as both an invitation and a threat because I did not yet know what growing up required.

Physical and Hormonal Changes

The original reflection emphasized sexual and hormonal changes as a source of discomfort. During puberty, changes in height, body composition, skin, voice, reproductive development, and sleep patterns can alter how an adolescent experiences the body. These changes do not occur at the same rate for everyone, which can lead to comparison and embarrassment. An adolescent who develops earlier or later than peers may feel exposed, immature, or different. Hormones influence

development, but they should not be used to explain every emotion or conflict. The social meaning attached to bodily change is equally important. Comments from relatives, expectations about appearance, teasing, and media images can make ordinary development feel like a public performance. In my experience, bodily change contributed to a desire for privacy and distance. I felt more comfortable in my room because being alone reduced the sense that other people were watching or evaluating me. What appeared to others as withdrawal was partly an attempt to adjust to a body and identity that no longer felt familiar (Steinberg & Morris, 2001).

Erikson's Identity Versus Role Confusion

Erikson described adolescence as a stage centered on identity versus role confusion. Identity involves a growing sense of continuity: the belief that the person one has been, the person one is now, and the person one hopes to become belong to a coherent life. Role confusion occurs when values, commitments, abilities, and social expectations feel disconnected. The theory does not mean that every adolescent must select a permanent career, worldview, and lifestyle immediately. Exploration is part of development. Adolescents may try different friendships, interests, beliefs, styles, or goals while learning what fits. My difficulty came from believing that maturity should arrive as a complete answer. When my parents said, "You need to grow up now," I heard the statement as evidence that a correct adult identity already existed and that I was failing to perform it. Erikson's theory helps me reinterpret that moment. The task was not to become a finished adult overnight; it was to begin integrating new responsibilities with an emerging understanding of myself.

The Search for Independence

Independence was one of the most difficult parts of my adolescence. During childhood, I relied heavily on my parents for decisions, emotional reassurance, practical support, and protection from consequences. As I grew older, they offered less direct help and expected me to manage more responsibilities. At the time, this felt like withdrawal. I wondered why support was being reduced precisely when life felt more complicated. In retrospect, I understand that healthy autonomy often develops through a gradual transfer of responsibility. Parents must remain available while allowing adolescents to make age-appropriate decisions, experience manageable consequences, and develop confidence. Conflict can occur because adolescents seek freedom faster than parents are willing to grant it, while parents may expect responsibility faster than the adolescent can consistently provide it. My own struggle involved wanting the freedom to define myself but resenting the duties attached to that freedom. I had to learn that autonomy is not simply the absence of parental control; it includes accountability for choices.

Family Distance and the Need for Privacy

The original essay described spending considerable time alone and maintaining distance from family. Privacy can serve a developmental purpose during adolescence because it allows reflection, emotional recovery, and experimentation with identity. However, isolation can also become a problem when it removes opportunities for support. In my case, the room became both a safe space and a barrier. I used solitude to reduce conflict and process feelings, but I sometimes avoided conversations that could have corrected misunderstandings. Family members may interpret adolescent privacy as rejection, secrecy, or disrespect, while adolescents may view parental questions as intrusion. Both interpretations can escalate conflict. A healthier balance would have involved clear boundaries: time alone without complete withdrawal, and family communication without constant monitoring. I now recognize that the need for privacy did not mean that I no longer needed attachment. I wanted to be treated as increasingly independent while still knowing that help remained available (World Health Organization, 2024).

Aggression, Irritability, and Emotional Regulation

I described my behavior during adolescence as becoming aggressive. It is important to examine that statement carefully. Irritability, arguments, sudden emotional reactions, and risk-taking can increase during adolescence, but they should not be dismissed as unavoidable or blamed only on hormones. Emotional regulation develops through practice, supportive relationships, sleep, coping strategies, and opportunities to understand the causes of distress. My aggressive responses often occurred when I felt misunderstood, controlled, embarrassed, or uncertain about expectations. Anger gave me a temporary sense of strength when I actually felt vulnerable. It also protected me from admitting fear. Yet aggression could damage relationships and make others focus on my behavior rather than the concern beneath it. Over time, I needed to learn how to pause, name the emotion, explain what I wanted, and tolerate disagreement. Maturity did not require the elimination of anger; it required expressing anger without using it to injure, intimidate, or avoid responsibility.

Peer Relationships and Social Comparison

Socialization became more intense during adolescence because peers offered information about belonging, attractiveness, competence, and acceptable behavior. Friendship could provide understanding that felt different from family support, but it also increased comparison. I worried about fitting into society while simultaneously wanting to be recognized as an individual. This is a common contradiction: adolescents may resist conformity in one area while depending strongly on peer approval in another. Social comparison can motivate growth, but it can also create the false impression that everyone else has achieved a stable identity. Peers usually reveal confidence more readily than confusion. My discomfort in social situations partly came from assuming that other

people were evaluating me as closely as I evaluated myself. Learning that most adolescents are managing their own insecurities would have reduced some of that pressure. Meaningful friendship develops not from performing maturity perfectly but from trust, reciprocity, and the ability to be imperfect without humiliation (Choudhury et al., 2006).

Moral Development and Questions of Right and Wrong

The original reflection mentioned striving to develop a moral attitude and distinguish right from wrong. Adolescence often expands moral reasoning because young people begin to evaluate rules rather than simply obey them. They may notice inconsistency between what adults teach and what adults do, question whether a rule is fair, and consider how choices affect people beyond their immediate circle. This process can look like rebellion, but questioning can be part of ethical development. My challenge was to separate personal desire from principled judgment. Sometimes I described a rule as unfair mainly because it limited what I wanted. At other times, disagreement reflected a genuine effort to understand why a rule existed. Developing a moral identity required listening, examining consequences, and accepting that maturity includes duties to other people. It also required recognizing that adults are not morally perfect and that I would eventually have to take responsibility for values rather than borrowing them uncritically from family or peers.

Stress, Sadness, and Mental Health

The earlier essay referred to stress and depression during adolescence. These terms should be distinguished. Stress, sadness, embarrassment, and mood changes can be normal responses to development and life events, while depression is a clinical condition involving persistent symptoms and meaningful impairment. Adolescents who experience sustained hopelessness, loss of interest, major changes in sleep or appetite, declining functioning, self-harm, or thoughts of suicide need prompt support from a qualified professional. Not every period of withdrawal means depression, but serious symptoms should never be dismissed as “just hormones.” In my reflection, I can identify psychological distress and discomfort, yet I should not retrospectively assign myself a diagnosis without assessment. The more accurate statement is that adolescence placed emotional demands on me that I did not always know how to manage. Access to trusted adults, counseling, and open conversations can help adolescents understand when an experience is within ordinary developmental variation and when additional care is necessary.

Brain Development and Decision-Making

Adolescent cognition becomes increasingly sophisticated, but systems involved in planning, impulse control, and evaluating long-term consequences continue developing into early adulthood. This does

not mean adolescents are incapable of good decisions. Their reasoning can be strong, especially in calm situations with adequate information. Difficulties are more likely when emotion is intense, peers are present, rewards are immediate, or consequences feel distant. I experienced this difference between knowing and acting. I could understand that an aggressive response would make a conflict worse and still react impulsively when I felt criticized. The lesson was not that I lacked reason, but that reasoning needed support from emotional regulation and experience. Parents and teachers can help by involving adolescents in decisions, explaining consequences, and allowing practice rather than relying only on commands. Respectful guidance strengthens judgment more effectively than humiliation.

Reinterpreting the Comment “You Need to Grow Up”

The statement from my parents became a major milestone because it signaled that they no longer viewed me only as a child. At the time, I interpreted the comment negatively. It seemed to announce the loss of childhood privileges and the arrival of expectations I had not chosen. I felt that people wanted mature behavior without acknowledging how confusing the transition was. Years later, I can understand the statement differently. My parents may have been expressing frustration, but they were also recognizing my increasing capacity. The problem was that “grow up” was too general to guide behavior. Adolescents benefit when expectations are specific: manage a schedule, communicate respectfully, complete responsibilities, ask for help, or consider the effect of a choice. A broad demand for maturity can produce shame because the adolescent cannot tell what success looks like. My reflection therefore includes both accountability and compassion. I needed to change some behaviors, but I also needed guidance that translated adulthood into learnable actions.

Continuity Between Adolescence and Adulthood

Adolescence does not end with every conflict resolved. Some identity questions continue through college, work, relationships, parenthood, and middle adulthood. Erikson’s broader theory describes development as lifelong, with later stages involving intimacy, generativity, and integrity. The skills developed during adolescence—reflection, autonomy, emotional regulation, moral judgment, and the ability to maintain relationships while becoming independent—support those later tasks. My adolescent struggles did not disappear immediately, but they became sources of self-knowledge. I learned that withdrawing can protect me temporarily but cannot replace communication; that anger may hide fear; and that independence requires accepting consequences. I also learned that identity is not a single discovery. It is revised through experience while retaining enough continuity to feel like one’s own life.

What I Would Tell My Adolescent Self

I would tell my younger self that confusion does not mean failure. Bodily discomfort, changing friendships, conflict with parents, and uncertainty about the future can be part of development, although severe distress deserves help. I would advise myself to speak more honestly instead of expecting others to infer what I was feeling. I would also explain that seeking support is not the opposite of independence. Mature people use relationships, information, and professional help when necessary. I would encourage patience with physical change and caution against comparing private insecurity with other people's public confidence. Most importantly, I would redefine growing up as a process of increasing responsibility combined with increasing self-understanding. Adulthood is not earned by suppressing emotion; it is strengthened by learning what emotions communicate and choosing how to act.

Conclusion

My adolescence was characterized by biological change, emotional discomfort, social pressure, family distance, and a struggle for identity and independence. Erikson's stage of identity versus role confusion provides a useful framework because it explains why I felt suspended between childhood and adulthood. The comment that I needed to grow up intensified my fear, but it also marked the beginning of greater responsibility. My aggressive reactions and withdrawal reflected difficulties with regulation and communication rather than a simple refusal to mature. With distance, I can see that adolescence was not a single crisis but a period of reorganization. I had to examine values, accept a changing body, renegotiate family relationships, and learn that autonomy includes accountability. The experience shaped my later understanding of selfhood: identity develops through exploration, relationships, decisions, and the gradual integration of past and future (Erikson, 1968).
